Intermediate and Deep Well Installation and Sampling Report

Dear Hasan:

Enclosed for your review is a copy of the Intermediate and Deep Well Installation and Sampling Report for the Former Defense Supply Center Philadelphia (DSCP).

If you have any questions, please feel free to contact me at (215) 702-4066 or Derek Pinkham at (215) 702-4070.

Sincerely,

Brian Blanchard, P.E.

1.0 INTRODUCTION

This work was completed in order to obtain additional information relating to the Potomac Raritan Magothy (PRM) aquifer, which is the deep aquifer underlying the site area. A total of six borings were advanced to the top of the weathered bedrock and four intermediate wells and six deep wells were installed on the former Defense Supply Center Philadelphia (DSCP) site, the former Passyunk Homes area and the CSX property. The intermediate and deep wells were installed at the site to obtain additional information on the lower PRM aquifer, determine groundwater flow direction in the deep aquifer, evaluate the chemistry of the aquifer in proximity to the DSCP site and to aid in the fate and transport analysis being completed at the site.

The drilling and well installation work was completed from January 2005 through April 2005. This work was completed by Tetra Tech FW, formerly Foster Wheeler Environmental Corporation, under Contract No. SP0600-00-D-5003 with the Defense Energy Support Center (DESC).

2.0 GEOLOGY

The DSCP site is located in the area of South Philadelphia, Pennsylvania, near the confluence of the Delaware and the Schuylkill Rivers. The site is situated in the Coastal Plain Physiographic Province just east of the Fall Line, a northeast-southwest trending escarpment that divides the rolling hills of the Piedmont Physiographic Province from the Coastal Plain. The topography is relatively flat with low relief. Much of the underlying Coastal Plain sediments have been developed and low-lying areas raised to grade with fill materials (i.e., cinders, bricks and other debris). Much of the study area is covered with roads, asphalt and buildings and the original pre-developed topography is highly altered. The area of the Coastal Plain underlying the study area consists of unconsolidated sediments of Cretaceous age or younger that dip at an angle steeper than the local topography, to the southeast, from the Fall Line towards the Atlantic Ocean. The orientation of the coastal plain beds result in the most recent sediments lying near the Atlantic Ocean with successively older bands of sediments cropping out further inland. In the South Philadelphia area, ancestral channels of both the Delaware and Schuylkill Rivers have altered Coastal plain sediments. This has resulted in the removal of some coastal plain sediment and the deposition of more recent alluvium, resulting in a complex series of subsurface channels filled with more recent sediments.

The following provides descriptions of the geologic units in the southern Philadelphia area:

Fill

The fill unit consists of modern fill type materials (i.e., brick, cinders etc.) and occupies formerly low-lying area. The fill unit generally lies on top of the Quaternary Alluvium. Within the study area, the thickness of the fill ranges from 0-40 feet, and is not laterally extensive. An increased thickness of this fill material is located in areas underlying the

railroad tracks to the west of the DSCP property (Integrated Science and Technology, 1998). Increased thicknesses were also identified in borings drilled along an ancient stream channel along the southeastern side of the DSCP property (Malcolm Pirnie 1997). Soil boring investigations revealed fill material ranging in thickness from 10–14 feet on the northwestern border of the DSCP property and the northwestern border of the Philadelphia Housing Authority just south of the Schuylkill Expressway.

Quaternary Alluvium (Qal)

This is the uppermost geologic unit in the study area. The unit is Holocene in age and consists of fine sand and silt and mud (Greenman et al, 1961). Regionally this unit can be up to 80 feet thick. Because the deposits are very fine grained and have very low permeabilities, the unit is not considered to be an important aquifer (Paulachok, 1991). However in some cases the unit may contain appreciable thicknesses (up to 3 feet) of interlayered sand and may show some localized perched water. This deposit at the site contains an extensive silt layer with variable amounts of clay (Malcolm Pirnie 1997). This dense silt layer, which varies in thickness, is present in the vadose zone above the water table over the entire DSCP and Passyunk Homes area. The silt layer dips to the south and intersects the water table on the southeastern portion of DSCP and Passyunk Homes. The silt layer has been extensively mapped and characterized as part of the Human Health Risk Assessment (Environ, 2001). In some areas the unit has been excavated for the emplacement of sewers and other utilities. The Qal overlies the Trenton Gravel.

Trenton Gravel (Qp)

The Trenton Gravels have been described in detail by Owens and Minard, 1979. They were able to divide the Trenton Gravels into two distinct units. The Trenton Gravels are gray to brown sands and gravel with minor amounts of silt and clay (Greenman et al., 1961). The Trenton Gravels are a variable unit and at the site consist of sand, silt and gravel mixtures, uniform sands and some dense silt. Generally the gravels are yellow to red brown in color and show varying degrees of iron staining. In some places the gravels are densely compacted or show some degree of cementation. The coarse gravels are of mixed lithologies and may consist of either clasts of red brown shales, quartzites, sandstones and some metamorphic and igneous rocks of Piedmont Province origin (from the west or northwest) or re-worked, more rounded less varied lithologies of Coastal Plain origin (from the north or northeast). Regionally the Trenton Gravels average about 40 ft in thickness (Paulachok, 1991) and can be as thick as 80 feet. At the DSCP site the sand and gravel mixtures average about 20 feet in thickness and lie unconformably beneath the Quaternary Alluvium and atop the Bridgeton Formation when it is present. Most of the unconfined upper aquifer consists of the Trenton Gravels and water yields vary widely. Due to the similar lithologies of the units the, Trenton Gravels and the underlying Bridgeton Formation (of Tertiary Age and minimal thickness, see below) are grouped for simplicity as Qp.

The Bridgeton Formation is composed of gravel and very coarse to fine sand (Owens and Minard, 1979). The Bridgeton is not laterally extensive and usually is present on topographic highs as deposits less than 10 feet thick. Ages applied to the Bridgeton Formation have always been speculative, with some authors favoring a Quaternary Pleistocene age and others a Tertiary Miocene age. Because of the lateral discontinuity of the unit, its minimum thickness, and its connection to the upper Trenton Gravels. A Qp designation has been assigned for simplicity in mapping and hydrogeologic modeling purposes.

At the site the Bridgeton formation is either indistinguishable or very thin, and is not named outright in visual logs.

Upper Clay (Kru)

Mesozoic sediments deposited during the Cretaceous period underlie the units mentioned above. The uppermost of these units is the Upper Clay. Recent U.S. Geological Survey nomenclature includes both the Upper Clay and the underlying Old Bridge Sand as part of the Magothy Aquifer (Paulachok, 1991). Greenman and others, 1961, have called the Upper Clay, "the upper most member of the Raritan Formation". The Upper Clay has been described as "light gray more or less sandy clays; dark gray carbonaceous; and massive, red, white and yellow clays" (Greenman et al, 1961). On site, the Upper Clay is not a continuous unit and when encountered, was located approximately 33 to 36 feet below grade and 1-3 feet thick. The presence of the Upper Clay may result in localized confining conditions in the underlying Old Bridge Sand. Where the Upper Clay is missing, the Old Bridge sand and the Upper Pleistocene Trenton Gravels are connected hydraulically and form a single unconfined aquifer.

Upper Sand Unit or Old Bridge Sand (Kro)

The Upper Sand Unit or Old Bridge Sand represents the upper sand unit of the PRM aquifer system. It consists of coarse to medium sand and minor amounts of fine to very fine sand. (Greenman et al, 1961). Regionally, the upper sand is found in scour surfaces within the underlying middle clay. The unit is commonly about 35 feet thick. On site the unit ranges in thickness from 5 to 15 feet, but is extremely variable or may be missing due to Pleistocene erosion and channeling. When encountered, the sand observed on site is gray well-sorted sand that grades to fine gravels in some places. During drilling activities these sands tend to be "flowing sands".

Middle Clay (Krm)

The Middle Clay unit is composed of tough white and red clay with uniformly massive texture. (Greenman et al, 1961, Sloto, 2003). In the Philadelphia area, the Middle Clay merges with the underlying lower clay and are indistinguishable. The Middle Clay, the underlying Sayerville Sand and the Lower Clay form one unit in the Philadelphia area. This clay has also been described as a red clay. This laterally extensive clay creates confined conditions in the underlying Farrington Sand, except to the west near the

Schuylkill River where the clay is missing and the Farrington Sand is unconfined (Paulachok, 1991 and Greenman et al., 1961). In this area the upper unconfined aquifer is in direct hydraulic connection with the lower Farrington Sand aquifer (Paulachok, 1991, Greenman et al., 1961). At the DSCP site, the middle clay has been observed at depths of 45 to 57 feet. The base of the Middle Clay is marked by a bed of lignite (Sloto, 2003). However, where the Middle Clay lies directly on the Lower Clay, which is the case in many areas of Philadelphia, it is difficult to differentiate the two units (Sloto, 2003).

Middle Sand Unit or Sayerville Sand (Krs)

The Middle Sand Unit or Sayerville Sand is not an extensive deposit in the South Philadelphia region. When observed, it is typically located about 1.5 miles inland from the Delaware River in scour channels within the lower clay unit (Paulachok, 1991). The Sayerville is composed of light colored coarse to very fine sand with a few layers of light gray clay (Sloto, 2003).

It may be likely that the Middle Sand Unit is missing at the site and the Middle Clay sits atop the Lower Clay Unit (Greenman, et all 1961). Our current geological framework model supports previous studies that suggest this unit is missing under the study area.

Lower Clay (Krl)

The lower clay is composed mainly of a tough continuous bed, which separates the underlying Farrington Sand from the Sayerville sand. The thickness of the lower clay ranges in thickness from 0-60 feet and is often indistinguishable from the middle clay. The clay member is composed mainly of tough brick red clay with some interstratified softer layers. (Greenman et al, 1961) Few boring locations describe the lower clay at the DSCP site as this unit is commonly combined with the middle clay.

Lower Sand Unit Farrington Sand (Krf)

The Lower Sand Unit or Farrington Sand consists of fine gravel and coarse sand that grade upward into medium to fine sand and a few layers of white clay (Greenman et al, 1961). This unit lies directly atop bedrock or the weathered bedrock surface. This unit represented the principle source of groundwater in the Philadelphia area (Paulachok, 1991).

Wissahickon Formation

The basement rock underlying the site is known as the Wissahickon Formation. These pre-Cretaceous rocks consist of mica, hornblendes, schists and gneisses (Sloto, 1988). The upper portion of the formation (a few feet to tens of feet) is marked by soft, gray micaceous clay that becomes firmer and more granular with depth (Greenman, et all, 1961).

2.1 SITE-SPECIFIC HYDROGEOLOGY

The site is situated in the Coastal Plain Physiographic Plain Province, near the confluence of the Schuylkill and Delaware Rivers. This area of the Coastal Plain Physiographic Province is comprised of unconsolidated clastic sediments of Cretaceous or younger age. The topography of the site is relatively flat with topographic contours ranging from approximately 20 to 25 feet above sea level.

The regional stratigraphy consists of alternating layers of sand, gravel, silt, and clay. The youngest deposits at the site are classified as the Quaternary alluvium consisting of fine sand, silt and clay. The alluvium at the site has been designated as silt with variable amounts of clay (Malcolm Pirnie 1997). This silt layer, which varies in thickness, is present in the vadose zone above the water table over the entire DSCP and Passyunk Homes area. The water table in the northeastern and southeastern portion of the site intersects this silt layer (Malcolm Pirnie 1997). Due to the presence of the silt layer and the large amounts of paving and buildings, local recharge from precipitation is inhibited.

The Trenton gravel underlies the Alluvium. The Trenton gravel (the unconfined aquifer) is comprised of gray to brown, poorly sorted sand with considerable sub-angular to rounded gravel. The grain size distribution of the Trenton gravel is highly variable, and results in varying hydraulic conductivity and yields. The upper surface of the water table aquifer mainly occurs in the Trenton gravel, but it extends into recent alluvium in a few places where former channels eroded the Trenton gravel (IST, 1998). In the study area, the upper aquifer appears to extend into and include the Upper Sand or Old Bridge Sand Unit. There may also be areas in which the Upper Sand Unit is overlain by the Upper Clay Unit and results in semi-confined conditions. The yields in the Trenton gravel and Old Bridge Sand vary from 1 gallon per minute (gpm) to 1,370 gpm (Paulachok, 1991). A more statistical evaluation reveals that 90% of the wells yield in excess of 0.5 gpm while only 10% exceed 40 gpm (Paulachok, 1991). According to Paulachok, the average hydraulic conductivity of the Trenton gravel is 142 feet per day (ft/day). The Trenton Formation is not used as a drinking water aquifer in the region because of water quality problems.

Based upon recent potentiometric data, the groundwater in the unconfined aquifer flows from the northwest to southeast on the former DSCP Site (Tetra Tech FW, 2004). Locally, groundwater gradients may be altered by pumping of recovery wells on the Sunoco property and an apparent depression in the groundwater table near well S-44 on the Sunoco property. The depth to groundwater underlying the former DSCP and Passyunk Homes properties is approximately 16 to 23 feet below grade.

The PRM aquifer system underlies the unconfined water table aquifer. The PRM consists of interbedded gravel, sand, silt and clay units, however, one or more of these units may be locally absent (Paulachok, 1991). The U.S. Environmental Protection Agency (USEPA) has designated the Potomac-Raritan-Magothy (PRM) aquifer system as a sole source aquifer in Camden and Gloucester Counties in New Jersey. While the PRM is no longer used in the Philadelphia area, it is an important water supply source in New

Jersey. The high concentrations of iron (as high as 429 milligrams/liter (mg/l), manganese (as high as 4 mg/l) and sulfate (as high as 1,720 mg/l) have made the groundwater unusable for most purposes under the Philadelphia region (Sloto, 2003). The pumping of the Lower Sand unit of the PRM in New Jersey has been known to cause the groundwater flow in the confined Lower Sand unit in Philadelphia to flow towards New Jersey (Low, Hippe and Yannacci, 2002). Based upon regional potentiometric data, groundwater flow in the PRM aquifer is anticipated to be from the northwest to southeast (Sloto, 2003).

The Upper Sand Unit of the PRM aquifer is overlain in places with the Upper Clay. There are areas of the site where the Upper Clay is absent. Where the Upper Clay is absent, the Upper Sand Unit is hydraulically connected to the overlying unconfined aquifer to form a single aquifer (Paulachok, 1991). In New Jersey, the Upper aquifer is the least extensive unit of the PRM (Sloto, 2003a).

3.0 LOCATIONS OF SOIL BORINGS AND MONITORING WELLS

A total of six deep soil borings were advanced at each intermediate/deep well location. The soil boring numbers correspond to the location of the deep well since only one boring was logged to install both deep and when appropriate, the intermediate monitoring well. For example Soil Boring DW-1 was advanced at the location of well installation IW-1/DW-1. Figure 1 depicts the locations of all the intermediate and deep wells on the former DSCP, CSX, and former Passyunk Homes properties. One intermediate and two deep wells were installed on the former DSCP property. One intermediate and two deep wells were installed on the CSX property. Two intermediate and two deep wells were installed in the vicinity of the former Passyunk Homes property. Because site access could not be obtained from the Philadelphia Housing Authority (PHA) for the installation of the wells on the former Passyunk Homes property, the wells were installed on public road right of ways with permission from the Philadelphia Department of Streets.

Deep wells were installed at the site to obtain additional information on the lower PRM aquifer, determine groundwater flow direction in the deep aquifer and to evaluate the chemistry of the deep aquifer in proximity to the DSCP site. Intermediate wells were installed at the site in the Upper Sand Unit of the PRM Aquifer in order to obtain additional information on the relationship between the shallow unconfined aquifer and the Upper Sand Unit of the PRM aquifer, determine groundwater flow, evaluate the chemistry of this hydraulic unit and determine the relationship between the different layers.

4.0 DEEP SOIL BORING AND WELL INSTALLATION

A soil boring was advanced to the top of the weathered bedrock at each of the six locations of the intermediate and deep wells. The geology logged from the one boring at each location was used to determine the screened intervals of the monitoring wells. A direct-push rig was utilized at each location to log the borehole until refusal, and then a mud rotary drill rig and split spoon sampling were used to complete the geologic logging to depth. Continuous soil samples were collected using a direct-push rig with a Macrotube sampler until refusal for that method was encountered. Continuous split spoon samples were then collected with the mud rotary rig. The visual borings were logged by a geologist using the Unified Soil Classification System. Appendix A contains the soil boring logs.

The wells were installed using a mud rotary rig. A ten-inch diameter wing tip was used to advance the soil boring into the Upper and Middle Clay, when present. When the Middle Clay was encountered, a 6-inch inner diameter (ID) steel casing was then set 1 to 3 feet into the Middle Clay at each of the deep well locations. When the Upper Clay was encountered, a second boring was drilled to install the intermediate well. A 6-inch ID steel casing was installed into the Upper Clay. Due to the minor thickness of the Upper Clay, the steel casing was driven 0.5 to 1 foot into the Upper Clay. The steel casings were grouted in place and allowed to set for a minimum of 24 hours. After the minimum of 24 hours, the inside of the steel casing was flushed with clean potable water.

Upon setting the steel casings in place, the borehole was advanced inside the steel casing using a six-inch diameter wing bit and mud rotary. The borehole was advanced to the desired depth in this manner to the top of weathered bedrock. Upon reaching bedrock and determining the depths of the screened intervals, the borehole was backfilled to the desired depth to set the deep well. The intermediate well was then installed to the desired depth using the mud rotary rig.

Upon completion, the boring logs were compared to the geological information previously obtained from the Site to determine which Unit was encountered at each boring. Generally, the Clay Units that were observed were encountered near the depth that was anticipated. Although the Deep Clay Unit was not expected to be encountered at all as a separate layer as it was in boring DW-3.

When both the Upper and Middle Clay Units were countered at a boring location, a well was installed below the Upper Clay (intermediate well) and one was installed below the Middle Clay Unit (deep well). This was done to evaluate the water quality between each of the clay units.

IW/DW-1 Location

The IW/DW-1 location was adjacent to the existing shallow monitoring well MW-23A on the western portion of the former DSCP property. The Upper Clay Unit was encountered at 40 to 42 feet below grade and the Middle Clay Unit was encountered from

50 to 54 feet below grade. The Lower Clay Unit was not encountered in this boring. The soil boring for this location was advanced to a depth of 104 feet below grade. The weathered bedrock was encountered at a depth of approximately 98 feet below grade. Petroleum stained soils were first encountered approximately 14 to 16 feet below grade. Soils with either petroleum odors and/or staining were encountered from approximately 14 to 39.5 feet below grade with the highest PID readings (+ 2,000 ppm) at 30 to 35 feet below grade. PID readings of the soil cuttings between the Upper and Middle Clay ranged from 25 to 41 ppm, but no odors or staining were noted. PID readings below the Middle Clay Unit mostly ranged from 0 to 3.7 ppm, with the exception of 56 to 60 feet below grade, which had a PID reading of 26.3 ppm. No staining or petroleum odors were noted in soil cuttings below the Middle Clay Unit.

Since both the Upper and Middle Clay Units were encountered at this location, both the intermediate (IW-1) and deep (DW-1) monitoring wells were installed at this location. A steel casing was set at a depth of 42 feet below grade for IW-1 and the well was screened from 42 to 47 feet below grade. A steel casing was set a depth of 52 feet below grade for DW-1 and the well was screened from 65 to 80 feet below grade. Appendix A contains the well construction diagrams.

IW/DW-2 Location

The IW/DW-2 location was changed from the proposed location in the Work Plan for the Intermediate and Deep Monitoring Wells because access could not be obtained from PHA, the current owner of the former Passyunk Homes property. The location of IW/DW-2 was moved to Hartranft Street, approximately 180 feet west of monitoring well MWS-15. The movement of these wells was coordinated with the Pennsylvania Department of Environmental Protection (PADEP) and the Philadelphia Streets Department. The Upper Clay Unit was encountered at 28 to 32 feet below grade and the Middle Clay Unit was encountered from 52 to 82 feet below grade. PID readings as high as 48 ppm were noted below the Middle Clay Unit.

Since both the Upper and Middle Clay Units were encountered at this location, both the intermediate (IW-2) and deep (DW-2) monitoring wells were installed at this location. A steel casing was set at a depth of 21 feet below grade for IW-2 and the well was screened from 35 to 50 feet below grade. A steel casing was set a depth of 55 feet below grade for DW-2 and the well was screened from 84 to 99 feet below grade. The Lower Clay Unit was not encountered in this location.

IW/DW-3 Location

The IW/DW-3 location was changed from the proposed location in the Work Plan for the Intermediate and Deep Monitoring Wells because access could not be obtained from PHA, the current owner of the former Passyunk Homes property. The location of IW/DW-3 was moved north of Hartranft Street, just east of Penrose Ferry Road, adjacent to monitoring well PH-05. The movement of these wells was also coordinated with the PADEP and the Philadelphia Streets Department. The Upper Clay Unit was encountered at 37.5 to 38.5 feet below grade, the Middle Clay Unit was encountered from 58 to 68

feet below grade, and the Lower Clay Unit was encountered from 79 to 84 feet below grade. PID readings were all non-detect until a depth of 92 feet below grade. A slight petroleum odor was also noted at this depth. This highest PID reading (64.1 ppm) was encountered at 110 feet below grade. Beneath this depth, PID readings slowly decreased.

Since the Upper, Middle, and Lower Clay Units were encountered at this location, both the intermediate (IW-3) and deep (DW-3) monitoring wells were installed at this location. DW-3 was installed below the Lower Clay Unit and IW-3 was installed between the Middle and Upper Clay Units. A steel casing was set at a depth of 38 feet below grade for IW-3 and the well was screened from 42 to 57 feet below grade. A steel casing was set at a depth of 61 feet below grade for DW-3 and the well was screened from 85 to 100 feet below grade. This was the only location in which the lower clay was observed. DW-3 was the only well screened below this lower clay unit.

IW/DW-4 Location

The IW/DW-4 location was adjacent to the existing shallow monitoring well CSX-MW-7 on the southern portion of the CSX property. Neither the Upper, Middle, or Lower Clay Units were encountered at this location. The soil boring for this location was advanced to a depth of 116 feet below grade. The weathered bedrock was encountered at a depth of approximately 110 feet below grade. Elevated PID readings were first encountered at a depth of 36 feet below grade at this location. Soils with either petroleum odors and/or staining were encountered from approximately 36 to 58 feet below grade with the highest PID readings (1,057 ppm) at 54 to 56 feet below grade. The PID readings of the soils cutting decreased significantly below 60 feet below grade.

Since neither the Upper, Middle, or Lower Clay Units were encountered at the IW/DW-4 location, no steel casing was installed at this location. The well was screened from 85 to 100 feet below grade.

IW/DW-5 Location

The IW/DW-5 location was adjacent to the existing shallow monitoring well CSX-MW-5 on the CSX property. The Upper Clay Unit was encountered at 58 to 61 feet below grade and the Middle Clay Unit was encountered from 77 to 81 feet below grade. The soil boring for this location was advanced to a depth of 108 feet below grade. The weathered bedrock was encountered at a depth of approximately 106 feet below grade. Petroleum stained soils were first encountered approximately 14 to 16 feet below grade. Soils with either petroleum odors and/or staining were encountered from approximately 14 to 39.5 feet below grade with the highest PID readings (+ 2,000 ppm) at 30 to 35 feet below grade. PID readings of the soil cuttings between the Upper and Middle Clay ranged from 25 to 41 ppm, but no odors or staining were noted. PID readings below the Middle Clay Unit were all below 1.0 ppm, with a majority of the results being non-detect. No staining or petroleum odors were noted in soil cuttings below the Middle Clay Unit.

Since both the Upper and Middle Clay Units were encountered at this location, both the intermediate (IW-5) and deep (DW-5) monitoring wells were installed at this location. A

steel casing was set at a depth of 61 feet below grade for IW-5 and the well was screened from 63 to 68 feet below grade. A steel casing was set a depth of 77 feet below grade for DW-5 and the well was screened from 85 to 100 feet below grade. The Lower Clay Unit was not encountered in this location.

IW/DW-6 Location

The IW/DW-6 location was adjacent to the existing shallow monitoring well MW-2B on the northern portion of the former DSCP property. The Upper and the Middle Clay units appeared to be combined at this location from a depth of 36 to 49 feet below grade. This boring was advanced to a total depth of 154 feet below grade. The top of the weathered bedrock was encountered at approximately 134 feet below grade. No PID readings, odors or stained soils were noted during the logging of the soils at this location.

Since the Upper and Middle Clay units were combined at this location, and the Lower Clay Unit was not encountered, only one well (DW-6) was installed at this location. The steel casing for the well was set into the clay unit at a depth of 39 feet below grade. The well was screened from 55 to 75 feet below grade.

4.1 WELL DEVELOPMENT

The monitoring wells were developed a minimum of 24 hours after the completion of each well. The purpose of well development was to stabilize and increase the permeability of the gravel pack around the well screen and to restore the permeability of the formation that may have been reduced by drilling operations. Each monitoring well installed as part of the field investigation was developed by using the two-pipe air lifting procedure. Air was injected through an inner pipe at high pressure to bubble out into the surrounding pipe. The bubbles reduced the weight of the water, causing the column of water and sediments to be lifted upward, allowing groundwater from the formation to flow into the well. The water generated from the development process was containerized in drums for off-site disposal. Water quality parameters including pH, conductivity, temperature, dissolved oxygen and oxidation-reduction potential were obtained during the development process. Table 1 provides a summary of the groundwater quality parameters during the well development and the total gallons removed from each of the wells. Please note that due to the injection of air during the development of the wells, dissolved oxygen concentrations were greatly elevated and do not correspond to actual dissolved oxygen concentrations in the formation.

4.2 WELL SURVEYING

The locations and elevations of each well were surveyed by James Stewart, a Pennsylvania licensed surveyor. The wells were surveyed relative to the horizontal locations using North American Datum of 1983 (NAD 83) and the vertical elevations using the North American Vertical Datum of 1988 (NAVD 88). Table 2 provides the survey information for the intermediate and deep wells.

5.0 GROUNDWATER FLOW

The groundwater elevations used to prepare the groundwater elevation figure for the PRM were determined by subtracting the depth to water from the surveyed measuring point (inner well casing). Table 3 provides the groundwater measurements obtained from the shallow, deep, and when present, the intermediate monitoring well at each location. Only the measurements from the deep monitoring wells were used to construct the groundwater elevation figure for the deep aquifer. A groundwater contour map for the deep monitoring wells is presented as Figure 1. The groundwater contours of the shallow aquifer have been compiled on a quarterly basis as part of the on-going work at the former DSCP site and provided in the Quarterly Progress Reports.

Based upon the review of the groundwater measurements obtained from the deep wells associated with the former DSCP site, the groundwater flow in the PRM aquifer appears to flow from northwest to southeast across the CSX property, the former DSCP and former Passyunk Homes properties. The hydraulic heads in the shallow aquifer are higher than the hydraulic heads in the deep aquifer, indicating a downward component of groundwater flow. The hydraulic heads between the intermediate and deep wells varied from 0.18' (DW/IW-5) to 1.84' (DW/IW-2).

6.0 GROUNDWATER SAMPLING AND ANALYSIS

The groundwater sampling effort was conducted from April 11 through April 13, 2005. Prior to sampling, the monitoring wells were purged with a Rediflo2 submersible pump equipped with a flow controller. The water quality parameters including pH, conductivity, temperature, dissolved oxygen and oxidation-reduction potential were measured every 3 to 5 minutes during the well purging using a Horiba U-22 with a flow through cell. The purging proceeded until three well volumes were purged from the well and all water quality parameters stabilized. Stabilization was achieved when three consecutive readings varied by less than 10%. Table 4 provides a summary of the water quality parameters collected while purging the wells for sampling.

Groundwater samples were collected from the shallow, intermediate and deep wells at each cluster of wells: MW-23A, IW-01, DW-01, MWS-15, IW-02, DW-02, PH-06 IW-03, DW-03, CSX-MW-7, DW-04, CSX-MW-5, IW-05, DW-05, MW-2B and DW-06.

6.1 SAMPLE DESIGNATION

The objective of the sample identification system is to provide a framework for developing sample numbers that are unique to that sample and convey information regarding sample type that will enable data users to easily identify sample locations.

Each sample was designated by an alphanumeric code, which identifies the well and date sampled. Sample types shall be identified by a two-letter code, while each sample number shall be identified by a two-digit number. An example of the identification system is provided on the following page.

FIRST SEGMENT

MW, PH, IW, DW
Etc.: Well Indicator

SECOND SEGMENT

Well Number: 1, 2, A, etc

THIRD SEGMENT

Month and Year of Sample: (1104) (November 2004)

For example, a water sample obtained from Well IW-1 in April 2005 is identified as IW-10405. If the sample was field filtered for metals, the designation is IW-10405F.

6.2 GROUNDWATER ANALYSIS

The groundwater samples collected were analyzed for volatile organic compounds (VOCs), total dissolved solids, total and dissolved iron and manganese. This section provides a summary of the analytical results of the groundwater sampling effort. Tables 5 and 6 provide a summary of the analytical results and Figures 2 and 3 present the well locations with VOC and metal analytical results, respectively. Appendix B contains the laboratory analytical data.

CSX-MW-5, IW-05, DW-05

The groundwater from monitoring well CSX-MW-05 contained concentrations of benzene (2,000 micrograms per liter; $\mu\text{g/l}$), ethylbenzene (41 $\mu\text{g/l}$), toluene (18 $\mu\text{g/l}$) and xylenes (140 $\mu\text{g/l}$). There were no detectable concentrations of methyl tert-butyl ether (MTBE) in the groundwater sampled from CSX-MW-05. The groundwater from the intermediate well (IW-05) adjacent to CSX-MW-5 contained concentrations of benzene (110 $\mu\text{g/l}$), ethylbenzene (0.73 $\mu\text{g/l}$), xylenes (1.2 $\mu\text{g/l}$) and MTBE (34 $\mu\text{g/l}$). The groundwater from the deep well (DW-05) adjacent to CSX-MW-5 contained concentrations of MTBE (49 $\mu\text{g/l}$).

The total iron concentration of groundwater from CSX-MW-5 was 31,700 $\mu\text{g/l}$ and the dissolved iron was 24,600 $\mu\text{g/l}$. The total manganese concentration of groundwater from CSX-MW-5 was 496 $\mu\text{g/l}$ and the dissolved manganese was 400 $\mu\text{g/l}$. The total iron concentration of groundwater from IW-05 was 1,500 $\mu\text{g/l}$ and the dissolved iron was 600 $\mu\text{g/l}$. The total manganese concentration of groundwater from IW-5 was 3,540 $\mu\text{g/l}$ and the dissolved manganese was 3,690 $\mu\text{g/l}$. The total iron concentration of groundwater from DW-5 was 245 $\mu\text{g/l}$ and the dissolved iron was 296 $\mu\text{g/l}$. The total manganese concentration of groundwater from DW-5 was 7,970 $\mu\text{g/l}$ and the dissolved manganese was 7,650 $\mu\text{g/l}$.

CSX-MW-7, DW-4

The groundwater from monitoring well CSX-MW-07 contained concentrations of benzene (20 µg/l), ethylbenzene (4.2 µg/l), toluene (0.82 µg/l) and xylenes (3.4 µg/l). There were no detectable concentrations of MTBE in the groundwater sampled from CSX-MW-07. The groundwater from the deep well (DW-04) adjacent to CSX-MW-7 contained concentrations MTBE (13 µg/l) and chloroform (0.59 µg/l).

The total iron concentration of groundwater from CSX-MW-7 was 13,600 µg/l and the dissolved iron was 12,600 µg/l. The total manganese concentration of groundwater from CSX-MW-7 was 944 µg/l and the dissolved manganese was 908 µg/l. The total iron concentration of groundwater from DW-4 was 12,400 µg/l and the dissolved iron was 14,500 µg/l. The total manganese concentration of groundwater from DW-4 was 4,790 µg/l and the dissolved manganese was 5,520 µg/l.

MW-2B, DW-6

There were no detectable concentrations of VOCs in the groundwater sample collected from MW-2B. The groundwater in the deep well (DW-6) adjacent to MW-2B contained low concentrations of MTBE (0.70 µg/l), trichloroethene (0.53 µg/l) and tetrachloroethene (1.5 µg/l).

The total iron concentration of groundwater from MW-2B was 8,090 µg/l and the dissolved iron was 6,860 µg/l. The total manganese concentration of groundwater from DW-6 was 619 µg/l and the dissolved manganese was 623 µg/l. The total iron concentration of groundwater from DW-6 was 710 µg/l and the dissolved iron was 602 µg/l. The total manganese concentration of groundwater from DW-6 was 3,820 µg/l and the dissolved manganese was 3,240 µg/l.

MW-23A, IW-01, DW-01

The groundwater from monitoring well MW-23A contained concentrations of ethylbenzene (100 µg/l), toluene (7.4 µg/l), xylenes (39.8 µg/l), cis-1,2-dichloroethene (2.0 µg/l) and methylene chloride (8.8 µg/l). There were no detectable concentrations of methyl tert-butyl ether (MTBE) in the groundwater sampled from MW-23A. The groundwater from the intermediate well (IW-01) adjacent to MW-23A contained concentrations of benzene (0.66 µg/l), ethylbenzene (1.2 µg/l), xylenes (10.3 µg/l), MTBE (120 µg/l) and cis-1,2-dichloroethene (2.8 µg/l). The groundwater from the deep well (DW-01) adjacent to MW-23A contained concentrations MTBE (210 µg/l), chloromethane (4.4 µg/l), tetrachloroethene (3.4 µg/l), and chloroform (0.82 µg/l).

The total iron concentration of groundwater from MW-23A was 36,400 µg/l and the dissolved iron was 22,300 µg/l. The total manganese concentration of groundwater from MW-23A was 1,130 µg/l and the dissolved manganese was 1,030 µg/l. The total iron concentration of groundwater from IW-01 was 17,600 µg/l and the dissolved iron was

22,200 µg/l. The total manganese concentration of groundwater from IW-01 was 4,210 µg/l and the dissolved manganese was 4,990 µg/l. The total iron concentration of groundwater from DW-1 was 2,950 µg/l and the dissolved iron was 2,800 µg/l. The total manganese concentration of groundwater from DW-01 was 5,430 µg/l and the dissolved manganese was 5,100 µg/l.

The groundwater from the shallow monitoring well (MW-23A) located northeast of the free-phase plume on DSCP, did not contain detectable concentrations of MTBE. The groundwater in the intermediate well (IW-01) and deep well (DW-01) contained increasing concentrations of MTBE with depth. Concentrations of cis-1,2-dichloroethene were detected in the groundwater of the intermediate well and tetrachloroethene was detected in the groundwater of the deep well at this location.

MWS-15, IW-02, DW-02

The groundwater from monitoring well MWS-15 did not contain any detectable concentrations of VOCs. The groundwater from the intermediate well (IW-02) in close proximity to MWS-15 contained concentrations of benzene (130 µg/l), ethylbenzene (6.8 µg/l), toluene (3.3 µg/l) and xylenes (36.6 µg/l). The groundwater from the deep well (DW-02) in close proximity to MWS-15 contained concentrations of benzene (520 µg/l), ethylbenzene (0.87 µg/l), toluene (6.4 µg/l) xylenes (12.2 µg/l), cis-1,2-dichloroethene (2.0 µg/l), and chloroform (0.79 µg/l).

The total iron concentration of groundwater from MWS-15 was 123 µg/l and the dissolved iron was non-detect. The total manganese concentration of groundwater from MWS-15 was 5,790 µg/l and the dissolved manganese was 1.78 µg/l. The total iron concentration of groundwater from IW-02 was 14,300 µg/l and the dissolved iron was 13,200 µg/l. The total manganese concentration of groundwater from IW-02 was 1,490 µg/l and the dissolved manganese was 1,540 µg/l. The total iron concentration of groundwater from DW-2 was 4,810 µg/l and the dissolved iron was (4,770 µg/l). The total manganese concentration of groundwater from DW-02 was 1,370 µg/l and the dissolved manganese was 1,410 µg/l.

The groundwater from the shallow monitoring well (MWS-15) located to the southwest of the free-phase plume on DSCP did not contain detectable concentrations of VOCs and had low concentrations of iron. The concentrations of benzene in the groundwater increased with depth at this location, with the highest concentrations being detected in the deep well. Cis-1,2-dichloroethene was also detected in the groundwater of the deep well.

PH-05, IW-03, DW-03

The groundwater from monitoring well PH-05 did not contain any detectable concentrations of VOCs. The groundwater from the intermediate well (IW-03) adjacent to PH-05 did not contain any detectable concentrations of VOCs. The groundwater from the deep well (DW-03) adjacent to PH-05 contained concentrations of benzene (12,000 µg/l), ethylbenzene (34 µg/l), toluene (38 µg/l), xylenes (67 µg/l), and cis-1,2-dichloroethene (22 µg/l).

The total iron concentration of groundwater from PH-15 was non-detect and the dissolved iron was non-detect. The total manganese concentration of groundwater from PH-05 was 27.7 µg/l and the dissolved manganese was 20.6 µg/l. The total iron concentration of groundwater from IW-03 was 54.6 µg/l and the dissolved iron was non-detect. The total manganese concentration of groundwater from IW-03 was 891 µg/l and the dissolved manganese was 949 µg/l. The total iron concentration of groundwater from DW-03 was 10,900 µg/l and the dissolved iron was 9,940 µg/l. The total manganese concentration of groundwater from DW-03 was 3,020 µg/l and the dissolved manganese was 2,880 µg/l.

The groundwater from the shallow monitoring well (MWS-15) located to the southwest of the free-phase plume on DSCP did not contain detectable concentrations of VOCs and had low concentrations of iron. The concentrations of benzene in the groundwater increased with depth at this location, with the highest concentrations being detected in the deep well. Cis-1,2-dichloroethene was also detected in the groundwater of the deep well.

7.0 CONCLUSIONS

Based upon the lithological data collected during the deep soil boring and well installation effort, it was determined that the Upper and Middle Clay Unit of the PRM was encountered at all the borings advanced to weathered bedrock on the former DSCP property as well as the former Passyunk Homes property. The Lower Clay Unit of the PRM was only encountered at the soil boring advanced for DW-3, located on the southeastern portion of the former Passyunk Homes property. No Upper or Middle Clay Unit was encountered at the deep soil boring advanced at the DW-04 location on the CSX property. The Upper and Middle Clay Units were also not encountered in a deep soil boring that was previously advanced for the installation of MW-43, southeast of DW-4 on the former Passyunk Homes property. We also know that the Middle Clay is not present on portions of the Sunoco property. The Middle Clay Unit is not present beneath the western half of the North Yard or beneath the West Yard (ENSR, 1992).

Based upon the groundwater contours of the deep aquifer created from measurements obtained from the deep wells installed in association with the former DSCP site, the groundwater flow is from the northwest to the southeast across the CSX, former DSCP and former Passyunk Homes properties. It should be noted that deep monitoring wells are located on the adjacent Sunoco property to the west, but no recent groundwater measurement data was available at the time of this report preparation. However, the May 10, 2004 groundwater contour figures for the deep wells on the Sunoco property confirm that there is a northwest to southeast groundwater flow gradient in the deep aquifer to the west of the former DSCP property.

The laboratory analytical data from the groundwater samples collected from the deep wells, and the southeast groundwater gradients determined from measurements of water levels in deep wells (Figure 1) indicate that there is volatile organic compound (VOC) contamination migrating from off-site in the deep aquifer underlying the former DSCP/Passyunk Homes properties. MTBE concentrations were detected in a number of the intermediate and deep monitoring wells on the western portion of the former DSCP Site and the CSX property. In some of these locations, the MTBE concentration increases with depth. Even though the groundwater measurements obtained from the newly installed deep monitoring wells and the nearby shallow wells indicate that there is a vertical flow component, no MTBE was detected in the shallow wells at these locations. MTBE is not a contaminant of concern and is not attributable to the former DSCP free-phase and dissolved phase plume because it has not been detected in the free-phase plume. Other petroleum-related compounds were also detected in the deep aquifer, hydraulically upgradient from the former DSCP plume. These compounds include benzene, toluene, ethylbenzene and xylenes.

The highest concentration of benzene detected in the deep groundwater monitoring wells was detected in DW-3 (12,000 ug/l). This well also exhibited the highest overall BTEX concentrations of all the deep wells. The shallow well (PH-5) and intermediate well (IW-3) at the same location as DW-3 had non-detect concentrations of BTEX. Not only were both the Upper and Middle Clay Unit logged at this location, but the Lower Clay Unit of

the PRM was also logged at this location. Based on the evaluation of the shallow and intermediate BTEX concentrations in the immediate vicinity, it can be said that the BTEX concentrations detected in the groundwater at DW-3 were not from vertical contaminant flow in the immediate vicinity. Based upon a review of the groundwater contours of the deep aquifer and the available analytical data of the deep aquifer at this time, it cannot be readily determined if the source of the elevated benzene is from the former DSCP free-phase/dissolved phase plume, or from another source. A former deep well (MW-6D) that was located in the center of DSCP's free-phase plume was sampled in 1995. The groundwater from MW-6D in 1995 contained a benzene concentration of 590 ug/l. This well has since been abandoned due to improper construction. DW-03 does appear to be downgradient of the former MW-6D, but the concentrations of benzene detected in DW-03, which is outside of the both the shallow DSCP free-phase and dissolved phase plume, is higher than those previously detected in deep groundwater samples collected immediately under the free-phase plume. The shallow groundwater sampling effort that was conducted on the former DSCP site in 2003 determined that the highest benzene concentrations (36,000 ug/l) in the shallow groundwater, outside the free-phase plume, was detected in MW-62, which is located on the western boundary of the northern portion of the Steen property. The highest BTEX concentrations in the groundwater in wells with no product occurred in the November 2003 sampling at MW-62 and PH-1, which is on the northwestern corner of Passyunk Homes. These locations are also hydraulically upgradient of DW-03, but it is unknown if there is similar groundwater contamination of the deep aquifer in those immediate areas.

The groundwater quality parameters measured during the purging of the deep monitoring wells for sampling (Table 4) indicate that the deep aquifer is an anaerobic aquifer under the vicinity of the site since the dissolved oxygen levels measured were 0 mg/l. A flow-through system was used to evaluate the water quality parameters during the purging in order to minimize contact with the air. The absence of dissolved oxygen and low to negative oxidation reduction potential values (see Table 4) indicate reducing conditions are present in the groundwater. These reducing conditions result in the dissolution of iron and manganese from the aquifer matrix into the groundwater. Higher dissolved iron and manganese concentrations are generally correlated with higher VOC concentrations in the aquifer. Bacterial degradation of organic wastes, such as petroleum products, landfill leachate, and other industrial wastes results in oxygen depletion and reductive dissolution. The highest concentration of dissolved iron detected in the groundwater of the shallow monitoring wells that were analyzed was in CSX-MW-5 (24,600 ug/l) and MW-23A (22,300 ug/l). The elevated iron and manganese concentrations correlate to the higher VOC concentrations in these wells. The highest concentrations of dissolved iron in the deeper groundwater were detected in IW-2 (13,200 µg/l), IW-1 (22,200 µg/l) and DW-4 (14,500 µg/l). The lowest dissolved iron concentrations in any of the groundwater samples obtained (non-detect) were in PH-5, IW-3 and MWS-15 which corresponds to the non-detect concentrations of VOCs detected during this sampling event and from previous sampling events of the shallow wells.

It is well documented that dissolved iron concentrations in the PRM aquifer are a regional issue. Based upon studies completed by the United States Geological Survey (U.S.G.S),

the total and dissolved iron concentrations detected in the groundwater samples collected from the PRM aquifer in the vicinity of the former DSCP site are within the concentrations detected in the immediate region and lower than those detected closer to the Delaware River (Sloto, 2003).

The shallow and the deep (PRM) aquifer underlying the former DSCP study area are not being utilized as a drinking water source in Pennsylvania. A further discussion of groundwater flows, contamination and fate and transport analysis will be discussed in the DSCP Remedial Investigation Report to be submitted at a later date.

Notes:

NA - Not Available

mS/cm - millisiemens per centimeter

NTU - nephelometric turbidity units

mV - millivolts

mg/L - milligrams per liter

ml/min - milliliter per minute

°C - degrees Centigrade

DTW - Depth to water below top of inner casing

DTP - Depth to product below top of inner casing

DTB - Depth to bottom below top of inner casing

DO - Dissolved Oxygen

ORP - Oxidation/Reduction Potential

Due to the introduction of air during the development process, DO readings are biased high and are not representative of normal aquifer conditions.

Notes:

NA - Not Available

mS/cm - millisiemens per centimeter

NTU - nephelometric turbidity units

mV - millivolts

mg/L - milligrams per liter

mL/min - milliliter per minute

Due to the introduction of air during the development process, DO readings are biased high and are not representative of normal aquifer conditions.

°C - degrees Centigrade

DTW - Depth to water below top of inner casing

DTP - Depth to product below top of inner casing

DTB - Depth to bottom below top of inner casing

DO - Dissolved Oxygen

ORP - Oxidation/Reduction Potential

DATA REPORTING QUALIFIERS- ORGANIC

For reporting results, the following "Results Qualifiers" are used:

- V** Value If the result is a value greater than or equal to the detection limit, report the value.
- U** Indicates the compound was analyzed for but was not detected. Report the minimum detection limit for the sample with the U, i.e. "10 U". This is not necessarily the instrument detection limit attainable for this particular sample based on any concentration or dilution that may have been required.
- J** Indicates an estimated value. This flag is used:
(1) When estimating a concentration for a tentatively identified compound (library search hits, where a 1:1 response is assumed.)
(2) When the mass spectral data indicated the identification, however the result was less than the specified detection limit greater than zero. If the detection limit was 10 ug/L and a concentration of 3 ug/L was calculated report as 3 J. This flag is used when similar situation arise on any organic parameter i.e. Pest, PCB and others.
- B** Indicates the analyte was found in the blank as well as the sample report as "12 B".
- E** Indicates the analyte's concentration exceeds the calibrated range of the instrument for that specific analysis.
- D** This flag identifies all compounds identified in an analysis at a secondary dilution factor.
- P** This flag is used for Pesticide/PCB target analyte when there is >25% difference for detected concentrations between the two GC columns. The lower of the two values is reported on Form 1 and flagged with a "P".
- N** This flag indicates presumptive evidence of a compound. This is only used for tentatively identified compounds (TICs), where the identification is based on a mass spectral library search. It applies to all TIC results. For generic characterization of a TIC, such as chlorinated hydrocarbon, the flag is not used.
- A** This flag indicates that a Tentatively Identified Compound is a suspected aldol-condensation product.

DATA REPORTING QUALIFIERS- INORGANIC

For reporting results, the following "Results Qualifiers" are used:

- I If the reported value was obtained from a reading that was less than the Contract Required Detection Limit (CRDL), but greater than or equal to the Instrument Detection Limit (IDL).
- U If the analyte was analyzed for, but not detected.
- E The reported value is estimated because of the presence of interference
- M Duplicate injection precision not met.
- N Spiked sample recovery not within control limits.
- S The reported value was determined by the Method of Standard Addition (MSA).
- W Post-digestion spike for Furnace AA analysis is out of control limits (85-115%), while absorbance is less than 50% of spike absorbance.
- + Duplicate analysis not within control limits.
- Correlation coefficient for the MSA is less than 0.995.
- *** Entering "S", "W" or "+" is mutually exclusive. NO combination of these qualifiers can appear in the same field for an analyte.
- D The reported value is from a secondary analysis with a dilution factor. The original analysis exceeded the calibration range.
- M Method qualifiers
 - "P" for ICP instrument
 - "A" for Flame AA
 - "PM" for ICP when Microwave Digestion is used
 - "AM" for Flame AA when Microwave Digestion is used
 - "FM" for furnace AA when Microwave Digestion is used
 - "CV" for Manual Cold Vapor AA
 - "AV" for automated Cold Vapor AA
 - "CA" for MIDI-Distillation Spectrophotometric
 - "AS" for Semi-Automated Spectrophotometric
 - "C" for Manual Spectrophotometric
 - "T" for Titrimetric
 - "NR" for analyte not required to be analyzed

SOP ID: P201-Data Review-03.doc
Revision #: 03

QA Control Code: A2040102

Revision Date: June 6, 2002
Effective Date: June 17, 2002

QA REVIEW GENERAL DOCUMENTATION

Project #: T2310

Completed

For thorough review, the report must have the following:

GENERAL:

- Are all original paperwork present (chain of custody, record of communication, airbill, sample management lab chronicle, login page)
- Check chain-of-custody for proper relinquish/return of samples
- Is the chain of custody signed and complete
- Check internal chain-of-custody for proper relinquish/return of samples /sample extracts
- Collect information for each project id from server. Were all requirements followed

COVER PAGE:

- Do numbers of samples correspond to the number of samples in the Chain of Custody and on login page
- Do lab numbers and client Ids on cover page agree with the Chain of Custody

CHAIN OF CUSTODY:

- Do requested analyses on Chain of Custody agree with form I results
- Do requested analyses on Chain of Custody agree with the log-in page
- Were the correct method log-in for analysis according to the Analytical Request and Chain of Custody
- Were the samples received within hold time
- Were any problems found with the samples at arrival recorded in the Sample Management Laboratory Chronicle

Non - Conformance /Comments:

1st Level QA Review Signature: Carole Collins Date: 4/29/05

2nd Level QA Review Signature: Kimpa Dukuy Date: 4/29/05

**CONFORMANCE /
NON-
CONFORMANCE
SUMMARY**

CHEMTECH

284 Sheffield Street, Mountainside New Jersey 07092

NEW JERSEY LAB ID#: 20012: NEW YORK LAB ID#: 11376

GC/MS VOA CONFORMANCE/NON-CONFORMANCE SUMMARY

CHEMTECH PROJECT NUMBER: T2310

MATRIX: Water

METHOD: 8260

- | | NA | NO | YES |
|--|----|----|-----|
| 1. Chromatograms Labeled/Compounds Identified. (Field samples and Method Blanks) | | | ✓ |
| 2. GC/MS Tuning Specifications
BFB Meet Criteria (NOTE THAT THERE ARE DIFFERENT CRITERIA FOR NY ASP CLP, CLP AND NJ) | | | ✓ |
| 3. GC/MS Tuning Frequency - Performed every 24 hours for 600 series and 12 hours for 8000 Series. | | | ✓ |
| 4. GC/MS Calibration - Initial Calibration performed before sample analysis and continuing calibration performed within 24 hours of sample analysis for 600 series and 12 hours for 8000 series. | | | ✓ |
| 5. GC/MS Calibration Requirements. | | | ✓ |
| a. Calibration Check Compounds for 8260 and CLP. | | | ✓ |
| b. System Performance Check Compounds for 8260 and CLP | | | ✓ |

8260 CALIBRATION CRITERIA

<u>SPCC Compounds</u>	<u>MIN RF</u>	<u>CCC Compounds</u>
Chloromethane	0.1	1,1-Dichloroethene
1,1-Dichloroethane	0.1	Chloroform
Bromoform	0.1	1,2-Dichloropropane
Chlorobenzene	0.3	Toluene
1,1,2,2-Tetrachloroethane	0.3	Ethylbenzene
Vinyl chloride		

For CCC compounds Initial Calibration Criteria – RSD less than or equal to 30%
For CCC compounds Continuing Calibration Criteria - %D less than or equal to 20%

6. Blank Contamination - If yes, list compounds and concentrations in each blank:

7. Surrogate Recoveries Meet Criteria

If not met, list those compounds and their recoveries which fall outside the acceptable ranges.

The Surrogate recoveries met the acceptable criteria except for CSX-MW-70405, CSX-MW-70405RE and IW-50405

CHEMTECH 284 Sheffield Street, Mountainside New Jersey 07092
NEW JERSEY LAB ID#: 20012; NEW YORK LAB ID#: 11376

GC/MS VOA CONFORMANCE/NON-CONFORMANCE SUMMARY (CONTINUED)

8. Matrix Spike/Matrix Spike Duplicate Recoveries Meet Criteria

If not met, list those compounds and their recoveries which fall outside the acceptable range.

Blank Spike provided

9. Internal Standard Area/Retention Time Shift Meet Criteria

Comments:

10. Analysis Holding Time Met

If not met, list number of days exceeded for each sample:
