Re: Former Defense Supply Center Philadelphia Facility
2006-2007 Intermediate and Deep Well Installation and Sampling Report

Dear Mr. Burke:

Enclosed is a copy of the 2006-2007 Intermediate and Deep Well Installation and Sampling Report for the Former Defense Supply Center Philadelphia (DSCP). This report summarizes the results of the well installation and groundwater sampling event that took place during 2006 and 2007.

If you have any questions, please feel free to contact me at (215) 702-4066 or Derek Pinkham at (215) 702-4070.

Sincerely,

Brian K. Blanchard, P.E.

1.0 INTRODUCTION

This work was completed in order to obtain additional information relating to the Potomac Raritan Magothy (PRM) aquifer, which is the deep aquifer underlying the site area. It is a supplement to the previous Intermediate and Deep Well Installation and Sampling Report for the former DSCP (June 30, 2005), Groundwater Sampling Report for the former DSCP (October, 2006), and ongoing groundwater investigation at the site. A total of seven borings were advanced to the top of the weathered bedrock and seven intermediate wells and seven deep wells were installed on the former Defense Supply Center Philadelphia (DSCP) site, the Philadelphia Housing Authority (PHA) property and the Steen property as shown on Figure 1. The intermediate and deep wells were installed at the site to obtain additional information on the lower PRM aquifer, determine groundwater flow direction in the deep aquifer, evaluate the groundwater quality in proximity to the DSCP site and to aid in the fate and transport analysis being completed at the site.

The drilling and well installation work was completed from November 2006 through February 2007. This work was completed by Tetra Tech EC, Inc. (TtEC), under Contract No. SP0600-00-D-5003 with the Defense Energy Support Center (DESC).

2.0 GEOLOGY

The DSCP site is located in the area of southern Philadelphia, Pennsylvania (known as South Philadelphia), near the confluence of the Delaware and the Schuylkill Rivers. The site is situated in the Coastal Plain Physiographic Province just east of the Fall Line, a northeast–southwest trending escarpment that divides the rolling hills of the Piedmont Physiographic Province from the Coastal Plain. The topography is relatively flat with low relief. Much of the underlying Coastal Plain sediments have been developed and low-lying areas raised to grade with fill materials (i.e., cinders, bricks and other debris). The study area is in an urban-industrial environment and most surfaces at the site are covered with asphalt, concrete, and buildings. The original pre-developed topography is highly altered. The area of the Coastal Plain underlying the study area consists of unconsolidated sediments of Cretaceous age or younger (Tertiary and Quaternary) that dip at an angle steeper than the local topography, to the southeast, from the Fall Line towards the Atlantic Ocean. The orientation of the coastal plain beds results in the most recent sediments lying near the Atlantic Ocean with successively older bands of sediments cropping out further inland. In the South Philadelphia area, ancestral channels of both the Delaware and Schuylkill Rivers have altered Coastal plain sediments. This has resulted in the removal of some coastal plain sediment and the deposition of more recent alluvium, resulting in a complex series of subsurface channels filled with more recent sediments.

The following provides descriptions of the geologic units in the South Philadelphia area:

Fill

The fill unit consists of modern fill type materials (i.e., brick, cinders etc.) and occupies formerly low-lying area. The fill unit generally lies on top of the Quaternary Alluvium. Within the study area, the thickness of the fill ranges from 0-40 feet, and is not laterally extensive. An increased thickness of this fill material is located in areas underlying the railroad tracks to the west of the DSCP property (Integrated Science and Technology, 1998). Increased thicknesses were also identified in borings drilled along an ancient stream channel along the southeastern side of the DSCP property (Malcolm Pirnie, 1997). Soil boring investigations revealed fill material ranging in thickness from 10–14 feet on the northwestern border of the DSCP property and the northwestern border of the Philadelphia Housing Authority just south of the Schuylkill Expressway.

Quaternary Alluvium (Qal)

This is the uppermost geologic unit in the study area. The unit is Holocene in age and consists of fine sand and silt and mud (Greenman et al, 1961). Regionally this unit can be up to 80 feet thick. Because the deposits are very fine grained and have very low permeabilities, the unit is not considered to be an important aquifer (Paulachok, 1991). However in places the unit may contain appreciable thicknesses (up to 3 feet) of interlayered sand and may show some localized perched water. This deposit at the site contains an extensive silt layer with variable amounts of clay (Malcolm Pirnie, 1997). This dense silt layer, which varies in thickness, is present in the vadose zone above the water table over the entire DSCP and Passyunk Homes area. The silt layer dips to the south and intersects the water table on the southeastern portion of DSCP and

Passyunk Homes. The silt layer has been extensively mapped and characterized as part of the Human Health Risk Assessment (Environ, 2002). In some areas the unit has been excavated for the emplacement of sewers and other utilities. The Qal overlies the Trenton Gravel.

Trenton Gravel (Qp)

The Trenton Gravels have been described in detail by Owens and Minard, 1979. They were able to divide the Trenton Gravels into two distinct units. The Trenton Gravels are gray to brown sands and gravel with minor amounts of silt and clay (Greenman et al., 1961). The Trenton Gravels are a variable unit and at the site consist of sand, silt and gravel mixtures, uniform sands and some dense silt. Generally the gravels are yellow to red brown in color and show varying degrees of iron staining. In some places the gravels are densely compacted or show some degree of cementation. The coarse gravels are of mixed lithologies and may consist of either clasts of red brown shales, sandstones, and metamorphic and igneous rocks of Piedmont Province origin (from the west or northwest) or re-worked, more rounded less varied lithologies of Coastal Plain origin (from the north or northeast). Regionally the Trenton Gravels average about 40 ft in thickness (Paulachok, 1991) and can be as thick as 80 feet. At the DSCP site the sand and gravel mixtures average about 20 feet in thickness and lie unconformably beneath the Quaternary Alluvium and atop the Bridgeton Formation when it is present. Most of the unconfined upper aquifer consists of the Trenton Gravels and water yields vary widely. Due to the similar lithologies of the units the, Trenton Gravels and the underlying Bridgeton Formation (of Tertiary Age and minimal thickness, see below) are grouped for simplicity as Qp.

The Bridgeton Formation is composed of gravel and very coarse to fine sand (Owens and Minard, 1979). The Bridgeton is not laterally extensive and usually is present on topographic highs as deposits less than 10 feet thick. Ages applied to the Bridgeton Formation have always been speculative, with some authors favoring a Quaternary Pleistocene age and others a Tertiary Miocene age. Because of the lateral discontinuity of the unit, its minimum thickness, and its connection to the upper Trenton Gravels, a Qp designation has been assigned for simplicity in mapping and hydrogeologic modeling purposes.

At the site the Bridgeton formation is either indistinguishable or very thin, and is not named outright in visual logs.

Upper Clay (Kru)

Mesozoic sediments deposited during the Cretaceous period underlie the units mentioned above. The uppermost of these units is the Upper Clay. Recent U.S. Geological Survey nomenclature includes both the Upper Clay and the underlying Old Bridge Sand as part of the Magothy Aquifer (Paulachok, 1991). Greenman and others, 1961, have called the Upper Clay, “the upper most member of the Raritan Formation”. The Upper Clay has been described as “light gray more or less sandy clays; dark gray carbonaceous; and massive, red, white and yellow clays” (Greenman et al, 1961). On site, the Upper Clay is not a continuous unit and when encountered, was located approximately 28 to 58 feet below grade and 1-6 feet thick. The presence of the Upper Clay may result in localized groundwater confining conditions in the underlying Old

Bridge Sand. Where the Upper Clay is missing, the Old Bridge sand and the Upper Pleistocene Trenton Gravels are connected hydraulically and form a single unconfined aquifer.

Upper Sand Unit or Old Bridge Sand (Kro)

The Upper Sand Unit or Old Bridge Sand represents the upper sand unit of the PRM aquifer system. It consists of coarse to medium sand and minor amounts of fine to very fine sand. (Greenman et al., 1961). Regionally, the upper sand is found in scour surfaces within the underlying middle clay. The unit is commonly about 35 feet thick. On site the unit ranges in thickness from 5 to 15 feet, but is extremely variable or may be missing due to Pleistocene erosion and channeling. When encountered, the sand observed on site is gray well-sorted sand that grades to fine gravels in some places. During drilling activities these sands tend to be "flowing sands".

Middle Clay (Krm)

The Middle Clay unit is composed of tough white and red clay with uniformly massive texture. (Greenman et al, 1961 and Sloto, 2003). In the Philadelphia area, the Middle Clay merges with the underlying lower clay and the two are indistinguishable. The Middle Clay, the underlying Sayerville Sand and the Lower Clay form one unit in the Philadelphia area. This clay has also been described as a red clay. This laterally extensive clay creates confined conditions in the underlying Farrington Sand, except to the west near the Schuylkill River where the clay is missing and the Farrington Sand is unconfined (Paulachok, 1991 and Greenman et al., 1961). In this area the upper unconfined aquifer is in direct hydraulic connection with the lower Farrington Sand aquifer (Paulachok, 1991, Greenman et al., 1961). At the DSCP site, the middle clay has been observed at depths of 45 to 57 feet. The base of the Middle Clay is marked by a bed of lignite (Sloto, 2003). However, where the Middle Clay lies directly on the Lower Clay, which is the case in many areas of Philadelphia, it is difficult to differentiate the two units (Sloto, 2003).

Middle Sand Unit or Sayerville Sand (Krs)

The Middle Sand Unit or Sayerville Sand is not an extensive deposit in the South Philadelphia region. When observed, it is typically located about 1.5 miles inland from the Delaware River in scour channels within the lower clay unit (Paulachok, 1991). The Sayerville is composed of light colored coarse to very fine sand with a few layers of light gray clay (Sloto, 2003).

It may be likely that the Middle Sand Unit is missing at the site and the Middle Clay sits atop the Lower Clay Unit (Greenman, et al., 1961). Our current geological framework model supports previous studies that suggest this unit is missing under the study area.

Lower Clay (Krl)

The lower clay is composed mainly of a tough continuous bed, which separates the underlying Farrington Sand from the Sayerville sand. The thickness of the lower clay ranges in thickness from 0-60 feet and is often indistinguishable from the middle clay. The clay member is composed mainly of tough brick red clay with some interstratified softer layers. (Greenman et

al., 1961) Few boring locations describe the lower clay at the DSCP site as this unit is commonly combined with the middle clay.

Lower Sand Unit Farrington Sand (Krf)

The Lower Sand Unit or Farrington Sand consists of fine gravel and coarse sand that grade upward into medium to fine sand and a few layers of white clay (Greenman et al., 1961). This unit lies directly atop bedrock or the weathered bedrock surface. This unit represented the principle source of groundwater in the Philadelphia area (Paulachok, 1991).

Wissahickon Formation

The basement rock underlying the site is known as the Wissahickon Formation. These pre-Cretaceous rocks consist of mica, hornblendes, schists and gneisses (Sloto, 1988). The upper portion of the formation (a few feet to tens of feet) is marked by soft, gray micaceous clay that becomes firmer and more granular with depth (Greenman, et all, 1961).

2.1 SITE- SPECIFIC HYDROGEOLOGY

The site is situated in the Coastal Plain Physiographic Plain Province, near the confluence of the Schuylkill and Delaware Rivers. This area of the Coastal Plain Physiographic Province is comprised of unconsolidated clastic sediments of Cretaceous or younger age. The topography of the site is relatively flat with land surface elevations ranging from approximately 20 to 25 feet above sea level.

As described above, the regional stratigraphy consists of alternating layers of sand, gravel, silt, and clay. The youngest deposits at the site are classified as the Quaternary alluvium consisting of fine sand, silt and clay. The alluvium at the site has been designated as silt with variable amounts of clay (Malcolm Pirnie, 1997). This silt layer, which varies in thickness, is present in the vadose zone above the water table over the entire DSCP and Passyunk Homes area. The water table in the northeastern and southeastern portion of the site intersects this silt layer (Malcolm Pirnie, 1997). Due to the presence of the silt layer and the large amounts of paving and buildings, local recharge from precipitation is inhibited.

The Trenton gravel underlies the Alluvium. The Trenton gravel is comprised of gray to brown, poorly sorted sand with considerable sub-angular to rounded gravel. The grain size distribution of the Trenton gravel is highly variable, and results in varying hydraulic conductivity and yields. The water table mainly occurs in the Trenton gravel, but may also occur within recent alluvium in places where former channels eroded the Trenton gravel (IST, 1998). Generally in the region Trenton gravel is underlain with the Upper Clay Unit, the top unit of PRM formation, an aquitard separating unconfined upper aquifer from confined aquifer within the PRM formation. In the study area, the Upper Clay is inconsistent and creates hydraulic connections, therefore the upper unconfined zone extends into the Upper Sand or Old Bridge Sand Unit. The yields in the Trenton gravel and Old Bridge Sand vary from 1 gallon per minute (gpm) to 1,370 gpm (Paulachok, 1991). A more statistical evaluation reveals that 90% of the wells yield in excess of 0.5 gpm while only 10% exceed 40 gpm (Paulachok, 1991). According to Paulachok, the

average hydraulic conductivity of the Trenton gravel is 142 feet per day (ft/day). The Trenton Formation is not used as a drinking water aquifer in the region because of water quality problems.

Based upon recent potentiometric data, the groundwater in the unconfined shallow zone flows from the northwest to southeast on the former DSCP Site (Tetra Tech FW, 2004). Locally, groundwater gradients may be altered by pumping of recovery wells on the Sunoco property and an apparent depression in the groundwater table near well S-44 on the Sunoco property. The depth to groundwater underlying the former DSCP and Passyunk Homes properties is approximately 16 to 23 feet below grade.

The PRM aquifer system underlies the shallow unconfined zone. The PRM consists of interbedded gravel, sand, silt and clay units; however, one or more of these units may be locally absent (Paulachok, 1991). The U.S. Environmental Protection Agency (USEPA) has designated the PRM aquifer system as a sole source aquifer in Camden and Gloucester Counties in New Jersey. While the PRM is no longer a significant groundwater source in the Philadelphia area, it is an important water supply source in New Jersey. The high concentrations of iron (as high as 429 milligrams/liter (mg/l), manganese (as high as 4 mg/l) and sulfate (as high as 1,720 mg/l) have made the groundwater unusable for most purposes under the Philadelphia region (Sloto, 2003). The pumping of the Lower Sand unit of the PRM in New Jersey has been known to cause the groundwater flow in the confined Lower Sand unit in Philadelphia to flow towards New Jersey (Low, Hippe and Yannacci, 2002). Based upon regional potentiometric data, groundwater flow in the PRM aquifer is anticipated to be from the northwest to southeast (Sloto, 2003). In New Jersey, the Upper aquifer is the least extensive unit of the PRM (Sloto, 2003).

In general, the Upper Sand Unit of the PRM aquifer is overlain with the Upper Clay Unit but there are areas where the Upper Clay Unit is absent and semi-confined conditions are present within the aquifer system (Paulachok, 1991). Due to the lack of a confining clay unit across the entire Site, the groundwater beneath the Site is considered a single groundwater system with vertical interconnectivities between sand layers present at certain locations across the site, such as the northwestern portion of the PHA property.

3.0 LOCATIONS OF SOIL BORINGS AND MONITORING WELLS

A total of seven direct push technology (DPT) soil borings were advanced across the site, one each at the intermediate/deep well locations. The soil boring designation identification corresponds to the appropriate deep well location. For example, soil boring DW-10 was advanced at the proposed location of well installation IW-10/DW-10. After completion of DPT soil borings, mud rotary drilling was performed for installation of intermediate/deep wells at the selected locations. Figure 1 depicts the locations of all the intermediate and deep wells installed at the site. A total of fourteen monitoring wells were installed during this effort; seven intermediate and seven deep wells (IW-07 through IW-13 and DW-07 through DW-13). Two intermediate/deep clusters were installed on former DSCP property (DW-12/IW-12 and DW-13/IW-13), two intermediate/deep clusters were installed on the former Passyunk Homes Area (DW-10/IW-10 and DW-11/IW-11), and three intermediate/deep clusters were installed on Steen property (DW-07/IW-07, DW-08/IW-08, and DW-09/IW-09).

Deep wells were installed at the site to obtain additional information on the lower PRM aquifer, determine groundwater flow direction in the deep aquifer and to evaluate the chemistry of the deep zone of the aquifer in proximity to the DSCP site. Intermediate wells were installed at the site in the Upper Sand Unit of the PRM Aquifer in order to obtain additional information on the relationship between the shallow unconfined aquifer and the Upper Sand Unit of the PRM aquifer, determine groundwater flow, evaluate the chemistry of this hydraulic unit and determine the relationship between the different layers.

4.0 DEEP SOIL BORING AND WELL INSTALLATION

The well installations were initiated using direct push technology (DPT). The DPT borings were installed using a macrocore sampler and were advanced until encountering clay (Upper or Middle clay unit), if present, or until refusal for that method was reached. The soils were continuously logged for lithology and screened with a photoionization detector (PID). The results of the DPT soil logs and the depths of clay units encountered at each location enabled pre-planning of the necessary lengths of the 6-inch inner diameter (ID) steel protective casing needed for installment of each intermediate/deep monitoring well. A mud rotary rig was used for drilling intermediate/deep monitoring wells after the advancement of the DPT borings. Once the depth to the clay was confirmed either from the soil logs or by split spoon sampling a ten-inch diameter wing tip was used to advance the soil boring into the Upper and Middle Clay, when present. When the Middle Clay was encountered, a 6-inch ID steel casing was then set 1 to 3 feet into the Middle Clay at each of the deep well locations. When the Upper Clay was encountered, a second boring was drilled to install the intermediate well. A 6-inch ID steel casing was installed into the Upper Clay. Due to the minor thickness of the Upper Clay, the steel casing was driven 0.5 to 1 foot into the Upper Clay. The steel casings were grouted in place and allowed to set for a minimum of 24 hours. After the minimum of 24 hours, the inside of the steel casing was flushed with clean potable water. At locations where clay was not present, a steel casing was not installed and at locations where only one clay unit was encountered, the steel casing was installed into the same clay unit for both the intermediate and deep wells.

Upon setting the steel casing in place, the borehole was advanced inside the steel casing using a six-inch diameter wing bit and mud rotary. With drilling advancement continuous split spoon samples were collected to the desired depth and confirmatory samples were obtained to the top of weathered bedrock. Upon reaching bedrock and determining the depths of the screened intervals, the borehole was backfilled to the desired depth to set the deep well. The intermediate well was then installed to the desired depth using the mud rotary rig in a separate borehole.

Logged lithological information from the DPT borings and split spoon soil samples was compiled for each deep well location implementing Unified Soil Classification System. Appendix A contains the soil boring logs.

Upon completion, the boring logs were compared to the existing geological information previously obtained for determination and correlation of Geologic Units at the Site. Generally, the Clay Units that were observed were encountered near the depth that was anticipated, although there were locations where no clay was encountered (DW-10 and DW-12) and where only Upper Clay Unit was encountered (DW-8, DW-9, and DW-11). When both the Upper and Middle Clay Units were encountered at a boring location, a well was installed below the Upper Clay (intermediate well) and one was installed below the Middle Clay Unit (deep well). This was done to evaluate the water quality between each of the clay units. However the deep soil borings revealed that none of the clay units continuously extend over the site and in places clay was not present. Where clay units were absent, the deep well was screened above the bedrock and the intermediate well was installed at a depth below which the clay layer is present in other boreholes at the site.

IW/DW-07 Location

The IW/DW-07 location is adjacent to the existing shallow monitoring well MW-62 on the northwestern portion of the Steen property. The Upper Clay Unit was encountered at 31 to 34 feet below grade and the Middle Clay Unit was encountered from 84 to 89 feet below grade. The Lower Clay Unit was not encountered in this boring. The soil boring for this location was advanced to a depth of 110 feet below grade. The weathered bedrock was encountered at a depth of approximately 104 feet below grade. Elevated PID readings were first noted at about 16 feet below grade. Soils with either petroleum odor and/or staining were encountered from approximately 19 to 28 feet below grade with the highest PID readings of 1,489 ppm. The remainder of the PID readings were not elevated at this location.

Since both the Upper and Middle Clay Units were encountered at this location, intermediate well IW-07 was cased into Upper Clay Unit and deep well DW-07 was cased into Middle Clay Unit. A steel casing was set at a depth of 33 feet below grade for IW-07 and the well was screened from 40 to 55 feet below grade. A steel casing was set a depth of 86.5 feet below grade for DW-07 and the well was screened from 93.5 to 103.5 feet below grade. Appendix A contains the well construction diagrams.

IW/DW-08 Location

The location of IW/DW-08 was moved approximately 25 feet north from the original location marked on the Work Plan (TtEC, 2006) due to a thick concrete covered surface. The closest existing well to IW/DW-08 location is MW-61. Only the Upper Clay Unit was encountered at this location, from 38.5 to 48 feet below grade. The DW-08 borehole was advanced to 124 feet below grade and weathered bedrock was encountered at about 120 feet below grade.

Elevated PID readings were first encountered at about 12 feet below grade. Soils with either petroleum odor and/or staining were encountered from approximately 12 to 37 feet below grade with PID readings over 2,000 ppm. The remainder of the PID readings were low to zero at this location.

Since only the Upper Clay Unit was encountered at this location, steel casings for both the intermediate IW-08 and deep DW-08 monitoring wells were installed into the Upper Clay Unit. A steel casing was set at a depth of 42 feet below grade for IW08 and the well was screened from 55 to 70 feet below grade. A steel casing was set at depth of 42.5 feet below grade for DW-08 and the well was screened from 100 to 115 feet below grade.

IW/DW-09 Location

The IW/DW-09 location is in the middle of the eastern edge of the Steen property adjacent to existing well PH-10. The Upper Clay Unit was encountered at 40.5 to 49 feet below grade. The Middle Clay Unit and the Lower Clay Unit were not present at this location.

Elevated PID readings were first encountered at approximately 15 feet below grade. Soils with either petroleum odor and/or staining were encountered from approximately 15 to 35 feet below

grade with PID readings of over 2,000 ppm. The remainder of the PID readings were low to zero at this location.

Since only the Upper Clay Unit was encountered at this location, steel casings for both the intermediate (IW-09) and deep (DW-09) monitoring wells were installed in the Upper Clay Unit. A steel casing was set at 43 feet below grade for IW-09 and the well was screened from 55 to 70 feet below grade. A steel casing was set at 42 feet below grade for DW-09 and the well was screened from 95 to 110 feet below grade.

IW/DW-10 Location

The IW/DW-10 location is adjacent to the existing shallow monitoring well MWS-1 on the northwestern corner of the PHA property. The location of IW/DW-10 is approximately 300 feet east from the IW/DW-09 and PH-10 locations. Neither the Upper, Middle, or Lower Clay Units were encountered at this location. The soil boring for this location was advanced to a depth of 136 feet below grade. The weathered bedrock was encountered at a depth of approximately 130 feet below grade. Elevated PID readings were first encountered at a depth of 14 feet below grade at this location. Soils with either petroleum odors and/or staining were observed at three different depths, the first and the shallowest zone approximately 20 to 40 feet below grade had the most extensive petroleum odor and highest PID readings (1,930 ppm); the second zone, 66 to 76 feet below grade, had a slight petroleum odor, PID readings are not available; the third zone, 88 to 124 feet below grade, also had a slight petroleum odor with PID readings ranging from 11.4 to 44.1 ppm.

Since clay was not present at this location, steel casings were not installed for IW-10 and DW-10 wells. Intermediate well IW-10 was screened from 43 to 58 feet below grade and deep well DW-10 was screened from 95 to 110 feet below grade.

IW/DW-11 Location

The IW/DW-11 location is adjacent to the existing shallow monitoring well PH-22 on the central western edge of the PHA property. IW/DW-11 is approximately 300 feet south from IW/DW-10 location. Only the Upper Clay Unit was encountered at this location, at a depth of 37 to 41 feet below grade. The soil boring for this location was advanced to a depth of 136 feet below grade. The weathered bedrock was encountered at a depth of approximately 130 feet below grade. Soils with elevated PID readings were encountered approximately from 8 to 70 feet below grade. The staining and highest PID readings ranging from 176 ppm to 1,930 ppm were from 16 to 40 feet below grade and had a petroleum odor or product. In addition, a slight petroleum odor was noted in soils from 48 to 54 feet below grade.

Steel casings for both IW-11 and DW-11 were set in the Upper Clay Unit. A steel casing was set at a depth of 40 feet below grade for IW-11 and the well was screened from 43 to 58 feet below grade. A steel casing was set a depth of 40 feet below grade for DW-11 and the well was screened from 95 to 110 feet below grade.

IW/DW-12 Location

The IW/DW-12 location was adjacent to the existing shallow monitoring well RW-3 on the south-southwestern edge of the former DSCP property. No clay layer was present at this location. The deep boring at this location was advanced to a total depth of 132 feet below grade. The top of the weathered bedrock was encountered at approximately 130 feet below grade. PID readings were noted through the most of the DW-12 borehole from 16 to 100 feet below grade. PID readings were not available below 100 feet below grade but staining and/or odor were not observed in this section. The most extensive odor, staining, and highest PID (>2,000 ppm) readings were noted from 20 to 40 feet below grade.

Since there was no clay encountered, both IW-12 and DW-12 were installed without setting a 6-inch steel casing. IW-12 was screened from 42 to 52 feet below grade and DW-12 was screened from 94 to 109 feet below the grade.

IW/DW-13 Location

The IW/DW-13 location was adjacent to the existing shallow monitoring well MW-11 on the eastern part of the former DSCP property. The Upper Clay Unit was encountered from 42 to 48 feet below grade. The Middle Clay Unit was encountered from 86 to 90.5 feet below grade at this location. The deep boring at this location was advanced to a total depth of 118 feet below grade. The top of the weathered bedrock was encountered at approximately 114 feet below grade. The most extensive odor, staining, and highest PID (>2,000 ppm) readings were noted from 16 to 42 feet below grade. Elevated PID readings were present throughout the boring and decreased with depth, but no petroleum odor was noted below 54 feet below grade.

The steel casing of IW-13 was set at 45 feet below grade within the Upper Clay unit and the well was screened from 60 to 75 feet below grade. The steel casing of DW-13 was set at 87.5 feet below grade within the Middle Clay Unit and the well was screened from 94 to 104 feet below grade.

4.1 WELL DEVELOPMENT

The monitoring wells were developed a minimum of 24 hours after the completion of each well. The purpose of well development was to stabilize and increase the permeability of the gravel pack around the well screen and to restore the permeability of the formation that may have been reduced by drilling operations. Each monitoring well installed as part of the field investigation was developed by using the two-pipe air lifting procedure. Air was injected through an inner pipe at high pressure to bubble out into the surrounding pipe. The bubbles reduced the weight of the water, causing the column of water and sediments to be lifted upward, allowing groundwater from the formation to flow into the well. The water generated from the development process was containerized in drums for off-site disposal.

4.2 WELL SURVEYING

The locations and elevations of each well were surveyed by James M. Stewart, Inc, a Pennsylvania licensed surveyor. The wells were surveyed relative to the horizontal locations

using North American Datum of 1983 (NAD 83) and the vertical elevations using the North American Vertical Datum of 1988 (NAVD 88). Table 1 provides the survey information for the intermediate and deep wells.

5.0 GROUNDWATER FLOW

The groundwater elevations used to prepare the groundwater elevation figure for the PRM were determined by subtracting the depth to water from the surveyed measuring point (inner well casing). Table 2 provides the groundwater measurements obtained for site monitoring wells in April 2007. Groundwater contour maps from the April 2007 gauging event for the shallow and deep zones are presented as Figures 2 and 3, respectively.

Based upon the review of the groundwater measurements obtained from the wells associated with the former DSCP site, the groundwater flow appears to flow from northwest to southeast. In both the shallow and deep zones, there appears to be a groundwater depression in the area of the Steen property. In eleven of the thirteen well locations, the hydraulic heads in the shallow zone are higher than the hydraulic heads in the deep zone, indicating a downward component of groundwater flow. The two areas which indicate an upward flow of groundwater are around the DW-04 and DW-07 locations on the southern edge of the CSX property and on the northern edge of the Steen property.

6.0 GROUNDWATER SAMPLING AND ANALYSIS

The groundwater sampling effort was conducted from April 3 through April 10, 2007. Prior to sampling, the monitoring wells were purged with a Grundfos Redioflo2 submersible pump equipped with a flow controller. Water quality parameters, including pH, conductivity, temperature, dissolved oxygen and oxidation-reduction potential, were measured every 5 minutes during the well purging using a Horiba U-22 with a flow through cell. The purging proceeded until water quality parameters stabilized. Stabilization was achieved when three consecutive readings varied by less than 10%. Table 3 provides a summary of the water quality parameters at the time the wells were sampled.

Groundwater samples were collected from 35 of the monitoring wells at the site. Shallow, intermediate and deep wells were sampled at 13 cluster well locations (MW-23A, IW-01, DW-01); (MWS-15, IW-02, DW-02); (PH-05, IW-03, DW-03); (CSX-MW-7, DW-04); (CSX-MW-5, IW-05, DW-05); (MW-2B, DW-06); (MW-62, IW-07, DW-07); (MW-61, IW-08, DW-08); (PH-10, IW-09, DW-09); (MWS-1, IW-10, DW-10); (PH-22, IW-11, DW-11); (IW-12, DW-12); and (IW-13, DW-13). Due to the presence of LNAPL in the well, groundwater samples were not collected from RW-3 and MW-11, which are the shallow wells associated with the IW/DW-12 and IW/DW-13 well clusters, respectively.

6.1 GROUNDWATER ANALYSIS

The groundwater samples were analyzed for volatile organic compounds (VOCs) via EPA method 8260B, and total and dissolved iron and manganese via EPA Method 6010B by Pace Analytical Services, Inc. of Export, PA. This section provides a detailed summary of the analytical results of the groundwater sampling effort for the newly installed wells along with their associated shallow well. A general discussion of the groundwater contamination follows this detailed summary. Benzene, toluene, ethylbenzene, xylenes, and methyl tertiary butyl ether (MTBE) were VOCs that were detected in well samples and are of compounds of concern. Tables 4 and 5 provide a summary of the analytical results and Figures 4 and 5 present the well locations with VOC and metal analytical results, respectively. Appendix B contains the laboratory analytical data.

MW-62, IW-07, DW-07

Benzene (570 micrograms per liter; µg/l) and MTBE (94 µg/l) were present in the sample collected from MW-62 at concentrations above the PADEP Act 2 Medium Specific Concentrations (MSC) for a Used Aquifer with total Dissolved Solids less than 2,500 mg/l (5 µg/l for benzene and 20 µg/l for MTBE). The groundwater analytical results have been compared to the Act 2 MSCs for reference purposes only. The cleanup standards that will be used for the groundwater beneath the site have not yet been established. Total xylenes present at levels below the MSC and estimated concentrations of toluene and ethylbenzene were also present in the sample. The groundwater samples from monitoring wells IW-07 and DW-07 indicated detectable concentrations of MTBE, the remainder of analyzed VOCs were below the reporting limits. MTBE was detected at a concentration of 73 µg/l, which is above the MSC for MTBE (20 µg/l), in the sample collected from IW-07 and 5.1 µg/l in the sample collected from DW-07.

Estimated concentrations of benzene were present in both samples and the sample collected from DW-07 contained an estimated concentration of total xylenes. The estimated concentrations are due to the laboratory result being above the instrument detection limit, but lower than the reporting limit for that compound.

The sample obtained from MW-62 contained concentrations of total iron (13 milligrams per liter; mg/l), dissolved iron (11 mg/l), total manganese (0.85 mg/l), and dissolved manganese (0.84 mg/l). In the sample from IW-07 all of iron (74 mg/l) and manganese (2.9 mg/l) were in dissolved metal form, with the dissolved concentrations being slightly higher than the total concentrations (74 mg/l for iron and 2.9 mg/l for manganese). Dissolved iron (9.8 mg/l) contributed 89% and dissolved manganese (4.2 mg/l) contributed 98% of total iron and manganese in the sample from DW-07.

MW-61, IW-08, DW-08

Benzene (6,100 µg/l) and ethylbenzene (1,100 µg/l) concentrations were found in the groundwater sampled from shallow well MW-61 at levels above the MSC. Toluene and xylenes were present in the sample at concentrations below the MSC. The only detectable and quantifiable organic compound at IW/DW-08 cluster location was MTBE (1,100 µg/l) in the groundwater sample from monitoring well IW-08. Benzene was identified at an estimated concentration in both samples and xylenes were present at an estimate concentration in the sample from DW-08.

The groundwater sample from MW-61 contained total iron (39 mg/l), dissolved iron (30 mg/l), total manganese (7.4 mg/l), and dissolved manganese (6.8 mg/l) concentrations. In the sample from IW-08 all of iron (38 mg/l) and manganese (5.8 mg/l) were in dissolved metal form with the dissolved concentrations being slightly higher than the total concentrations (38 mg/l for iron and 5.8 mg/l for manganese). Dissolved iron (1.6 mg/l) contributed 94% of total iron while manganese (4.2 mg/l) was all in dissolved form in sample from DW-08.

PH-10, IW-09, DW-09

Benzene (27,000 µg/l) and ethylbenzene (2,200 µg/l) were found in the groundwater sample from shallow well PH-10 at concentrations above the MSC. Toluene (700 µg/l) and xylenes (3,200 µg/l) were present in the sample at concentrations below the MSC. Estimated concentrations of benzene and MTBE were present in the sample collected from DW-09. Benzene (1,100 µg/l) and MTBE (60 µg/l) were present in the sample collected from IW-09 at concentrations above the MSC. Toluene, xylenes and an estimated concentration of ethylbenzene were also present in this sample.

In well sample PH-10 total iron was 35 mg/l and dissolved iron was 33 mg/l, total manganese was 0.39 mg/l and dissolved manganese was 0.36 mg/l. A similar result was found in the groundwater sample from IW-09; total iron was 34 mg/l and dissolved iron was 33 mg/l, while manganese (0.82 mg/l) was all in dissolved form. Total metal concentrations of iron (2.8 mg/l) and manganese (6.7 mg/l) in the groundwater sample from DW-09 were mainly present in dissolved form as 2.4 mg/l of iron and 6.5 mg/l of manganese respectively.

MWS-1, IW-10, DW-10

Concentrations of benzene (2,200 μg/l) and ethylbenzene (1,500 μg/l) were found in the groundwater sample from shallow well MWS-1 at levels above the MSC. Toluene and xylenes were present in the sample at concentrations below the MSC. The sample collected from IW-10 contained the highest concentrations of benzene detected during this sampling event (31,000 μg/l). Toluene, ethylbenzene and xylenes were also detected in this sample at concentrations below the MSC. The groundwater from the deep well DW-10 contained detectable concentrations of ethylbenzene (14 μg/l), xylenes (11 μg/l), and MTBE (21 μg/l), as well as an estimated concentration of benzene (4.2 μg/l). The result for MTBE was above the MSC for MTBE of 20 μg/l.

In well sample MWS-1 total iron was 56 mg/l and dissolved iron was 54 mg/l while manganese (1.1 mg/l) was all in dissolved form. Well sample IW-10 contained total iron (31 mg/l), dissolved iron (30 mg/l), total manganese (0.61 mg/l), and dissolved manganese (0.57 mg/l). The sample from deep well DW-10 contained concentrations of total iron (33 mg/l), dissolved iron (29 mg/l), total manganese (3.7 mg/l), and dissolved manganese (3.5 mg/l).

PH-22, IW-11, DW-11

Concentrations of benzene (760 μg/l) were found in the groundwater sample from shallow well PH-22 at levels above the MSC. Toluene, ethylbenzene, and xylenes were present in the sample at concentrations below the MSC. The groundwater sample from intermediate well IW-11 contained concentrations of benzene (23,000 μg/l) at levels above the MSC. Toluene, ethylbenzene, xylenes and an estimated concentration of MTBE were also present in this sample at levels below the MSC. The groundwater sample from DW-11 contained the following compounds at concentrations above the MSC: benzene (710 μg/l) and MTBE (29 μg/l). Toluene, ethylbenzene, and xylenes were present in the sample at concentrations below the MSC.

In well sample PH-22 total iron concentrations were 13 mg/l and dissolved iron was 12 mg/l, while manganese (0.16 mg/l) was all in dissolved form. The total iron concentration of the groundwater sample from IW-11 was 35 mg/l, the dissolved iron was 34 mg/l, total manganese 2.0 mg/l, and dissolved manganese was 1.9 mg/l. In the groundwater sampled from DW-11 all iron (49 mg/l) and manganese (1.4 mg/l) were in dissolved metal form, with the total iron concentrations being slightly less (48 mg/l).

IW-12, DW-12

Benzene (17,000 μg/l) and MTBE (200 μg/l) were detected in the sample from IW-12 at concentrations above the MSC. Toluene, ethylbenzene, and xylenes were present in the sample at concentrations below the MSC. Benzene (220 μg/l) was present in the sample collected from DW12 at a concentration above the MSC. Toluene, ethylbenzene, xylenes and an estimated concentration of MTBE were also present in this sample at levels below the MSC. Shallow well RW-3 was not sampled due to the presence of LNAPL in the well.

The total iron concentration of the groundwater sample from IW-12 was 4.6 mg/l, the dissolved iron was 3.0 mg/l, total manganese 0.84 mg/l, and dissolved manganese was 0.79 mg/l. In the sample from DW-12 all of iron (23 mg/l) and manganese (1.7 mg/l) were in dissolved metal form.

IW-13, DW-13

The only VOC at a concentration above MSC at this location was benzene (81 μg/l) in the sample collected from IW-13. MTBE (9.5 μg/l) and an estimated concentration of toluene were also present in this sample. The original and duplicate sample collected from DW-13 contained estimated concentrations of benzene, ethylbenzene, and MTBE. Shallow well MW-11 was not sampled due to the presence of LNAPL in the well.

The groundwater sample from well IW-13 contained concentrations of total iron (1.2 mg/l), dissolved iron (1.1 mg/l), total manganese (6.8 mg/l), and dissolved manganese (6.7 mg/l). The sample from deep well DW-13 contained concentrations of total iron (2.1 mg/l), dissolved iron (1.8 mg/l), total manganese (1.0 mg/l), and dissolved manganese (0.96 mg/l). The duplicate sample of DW-13 had similar results.

Summary of Groundwater Sampling Results

Benzene is the main component of the groundwater contamination detected in the vicinity of the Site in all three of the sampled zones. While not as prevalent, ethylbenzene and MTBE were detected at concentrations above the MSC in several of the wells. Ethylbenzene was only present at levels above the MSC in the samples collected from the shallow monitoring wells.

Within the shallow zone benzene was detected at quantifiable concentrations in seven of the thirteen groundwater sample locations. Detected benzene concentrations ranged from 380 μg/l at CSX-07 to 27,000 μg/l at PH-10. High concentrations are present in the central portion of the Steen property extending to the northwestern portion of the PHA property and elevated concentrations of benzene are also present in the central portion of the CSX property. A map showing the concentrations of benzene in shallow groundwater is presented as Figure 6. Note that as in previous sampling events, the wells containing LNAPL were not sampled, therefore groundwater benzene concentrations were not determined in areas where LNAPL is present on the groundwater surface.

MTBE was present at a concentration above the MSC in one of the shallow wells, MW-62 at a concentration of 94 μg/l. Ethylbenzene was present at a concentration above the MSC in samples collected from three groundwater wells, MWS-1 (1,500μg/l), MW-61 (1,100μg/l) and PH-10 (2,200μg/l).

In the intermediate zone wells, benzene and MTBE were the only compounds present at concentrations above the MSC. Quantifiable concentrations of benzene were present in seven of the eleven sampling locations. Quantifiable benzene concentrations ranged from 44 μg/l at IW-05 to 31,000 μg/l at IW-10. A map showing the concentrations of benzene in intermediate

groundwater zone is presented as Figure 7. MTBE was detected at concentrations above the MSC in six of the eleven sampling locations. Quantifiable MTBE concentrations ranged from 42 μg/l at IW-05 to 1,100 μg/l at IW-08. The highest concentration of MTBE detected during this sampling event in all zones was present in the sample collected from IW-08.

In the deep zone wells, benzene and MTBE were the only compounds present at concentrations above the MSC. Concentrations of benzene were present at concentrations above the MSC in four of the thirteen sampling locations. Quantifiable benzene concentrations ranged from 34 μg/l at DW-02 to 9,100 μg/l at DW-03. A map showing the concentrations of benzene in deep groundwater zone is presented as Figure 8. MTBE was detected at concentrations above the MSC in five of the thirteen sampling locations. Quantifiable MTBE concentrations ranged from 21 μg/l at DW-10 to 260 μg/l at DW-01.

A majority of the iron and manganese in the groundwater samples was found to be in dissolved form, with some exceptions for iron in two wells (MW-15S and PH-5). Total iron in the groundwater samples ranged from 0.23 mg/l to 26 mg/l and dissolved iron ranged from non-detect to 24 mg/l. Total manganese in the groundwater samples ranged from 0.018 mg/l to 1.9 mg/l and dissolved manganese ranged from 0.0093 mg/l to 1.9 mg/l.

Several wells contained concentrations of non-targeted and non-petroleum related compounds. Due to the transient nature of these detections, the results have not been included in the summary tables for this site, but are included as part of the laboratory data in Appendix B. The following are the well locations along with the VOC sampling results. IW-01 had concentrations of chloromethane of 10 μg/l, and methylene chloride of 45 μg/l, DW-06 had concentrations of tetrachloroethene of 15μg/l, IW-09 had concentrations of chloromethane of 22 μg/l, DW-11 had concentrations of trans 1,2-dichloroethene of 27 μg/l, IW-12 had concentrations of acetone of 44 μg/l, and vinyl chloride of 71 μg/l, DW-12 had concentrations of chloromethane of 5.9 μg/l, CSX-MW-07 had concentrations of acetone of 12 μg/l and chloromethane of 11 μg/l, MW-23A had concentrations of acetone of 14 μg/l, chloromethane of 14 μg/l, 1,1-dichloroethane of 7.1 μg/l and 1,1,2-trichloroethane of 11 μg/l, MW-61 had concentrations of chloromethane of 22 μg/l, and PH-10 had concentrations of chloromethane of 44 μg/l.

7.0 CONCLUSIONS

The lithological data collected during the installation of intermediate/deep wells showed that none of the PRM clay units identified at site are laterally consistent. This further complements indications from previous work at the site that there is communication between the shallow and deep aquifers in some areas.

After correlation of data it seems that the Upper Clay Unit is laterally consistent at the Steen property. From the western edge of the property the Upper Clay Unit extends south-eastward to the PHA property and pinches out east toward the DW-10 location where it is missing. At this point insufficient data were available for further correlation of the clay units at the site.

Based upon the groundwater contours created from water level measurements obtained from the deep wells, the groundwater flow in the Lower Sand aquifer is generally from the northwest to the southeast, with a groundwater depression located on the Steen property.

During the April 2007 sampling event, the highest concentrations of benzene were observed in both shallow and intermediate wells at Steen property and northwestern corner of the PHA property. Benzene exceeded the PADEP Act 2 Medium Specific Concentrations (MSC) of 5 µg/l for a Used Aquifer with Total Dissolved Solids concentration less than 2,500 mg/l in the following well samples: IW-02, DW-02, DW-03, IW-05, IW-09, IW-10, IW-11, DW-11, IW-12, DW-12, IW-13, CSX-05, CSX-07, MWS-1, MW-61, MW-62, PH-5 and PH-10.

During previous groundwater sampling efforts conducted in 2004 and 2005 MTBE was detected at several monitoring wells, including the intermediate/deep locations at western side of the Site. During the April 2007 sampling event, MTBE exceeded the MSC of 20 µg/l in the following well samples: IW-01, DW-01, DW-04, IW-05, DW-05, IW-07, IW-08, IW-09, DW-10, DW-11, IW-12, and MW-62. The highest concentration of MTBE was detected in the groundwater sampled from IW-08, located on the western portion of the Steen property. Results from the 2007 groundwater sampling revealed the same tendency of MTBE concentrations increasing with depth at existing intermediate/deep wells and in new installed wells. Other petroleum-related compounds were also detected in the deep aquifer, hydraulically upgradient from the former DSCP plume. These compounds include benzene, toluene, ethylbenzene and xylenes.

A further discussion of groundwater flow, contamination, and fate and transport analysis will be discussed in the DSCP Remedial Investigation Report to be submitted at a later date.

Langhorne, PA 19047

Dear Mr. Pinkham:

Enclosed are analytical results for samples submitted to Pace Analytical by Tetra Tech EC, Inc.. The samples were received on April 7, 2007. The results reported in this project meet the requirements as specified in Chapter 5 of the NELAC Standards. Any deviations or discrepancies from the NELAC standards are documented in the case narrative(s) of this report. Parameters printed in italics represent Non-NELAC accredited parameters. Please reference Pace project number 07-2793 when inquiring about this report.

[1] U.S. Environmental Protection Agency, 1996, Test Methods for Evaluating Solid Waste, SW-846, 3rd ed., Office of Solid Waste and Emergency Response, Washington, DC.

Sample Comments: Results reported on an as received basis. One surrogate was outside QC limits(low) in the neat analysis of this sample. All surrogate recoveries were acceptable in the dilution. Therefore, matrix interferences are suspected. It appears that the high concentration of Benzene is the primary interferant for the the surrogate in question.

Langhorne, PA 19047

Dear Mr. Pinkham:

Enclosed are analytical results for samples submitted to Pace Analytical by Tetra Tech EC, Inc.. The samples were received on April 12, 2007. The results reported in this project meet the requirements as specified in Chapter 5 of the NELAC Standards. Any deviations or discrepancies from the NELAC standards are documented in the case narrative(s) of this report. Parameters printed in italics represent Non-NELAC accredited parameters. Please reference Pace project number 07-2889 when inquiring about this report.

Client Site: Defense Supply Center
Client Ref.: 2277 XXXXXXXX

Pace Sample Identification	Client Sample Identification
0704-1929	MW-61-01 - 03
0704-1930	IW-09-01 - 03
0704-1931	DW-09-01 - 03

Pace Sample Identification	Client Sample Identification
0704-1932	PH-10-01 - 03
0704-1933	MW-20-01 - 03
0704-1934	MW-20D-01 - 03

General Comments: Cooler temperature 2 ° C upon receipt. Ice was present. This project was revised on 5/17/07 to add compounds to the volatile compound list.

Please call me if you have any questions regarding the information contained within this report.

Sincerely,

Timothy P. Reed
Project Manager

Dear Mr. Pinkham:

Enclosed are analytical results for samples submitted to Pace Analytical by Tetra Tech EC, Inc.. The samples were received on April 12, 2007. The results reported in this project meet the requirements as specified in Chapter 5 of the NELAC Standards. Any deviations or discrepancies from the NELAC standards are documented in the case narrative(s) of this report. Parameters printed in italics represent Non-NELAC accredited parameters. Please reference Pace project number 07-2894 when inquiring about this report.

Mr. Derek Pinkham
Tetra Tech EC, Inc.
820 Town Center Drive
Suite 100
Langhorne, PA 19047

Dear Mr. Pinkham:

Enclosed are analytical results for samples submitted to Pace Analytical by Tetra Tech EC, Inc.. The samples were received on April 7, 2007. The results reported in this project meet the requirements as specified in Chapter 5 of the NELAC Standards. Any deviations or discrepancies from the NELAC standards are documented in the case narrative(s) of this report. Parameters printed in italics represent Non-NELAC accredited parameters. Please reference Pace project number 07-2792 when inquiring about this report.
